Multithreading

99788 – Francisco Gonçalves

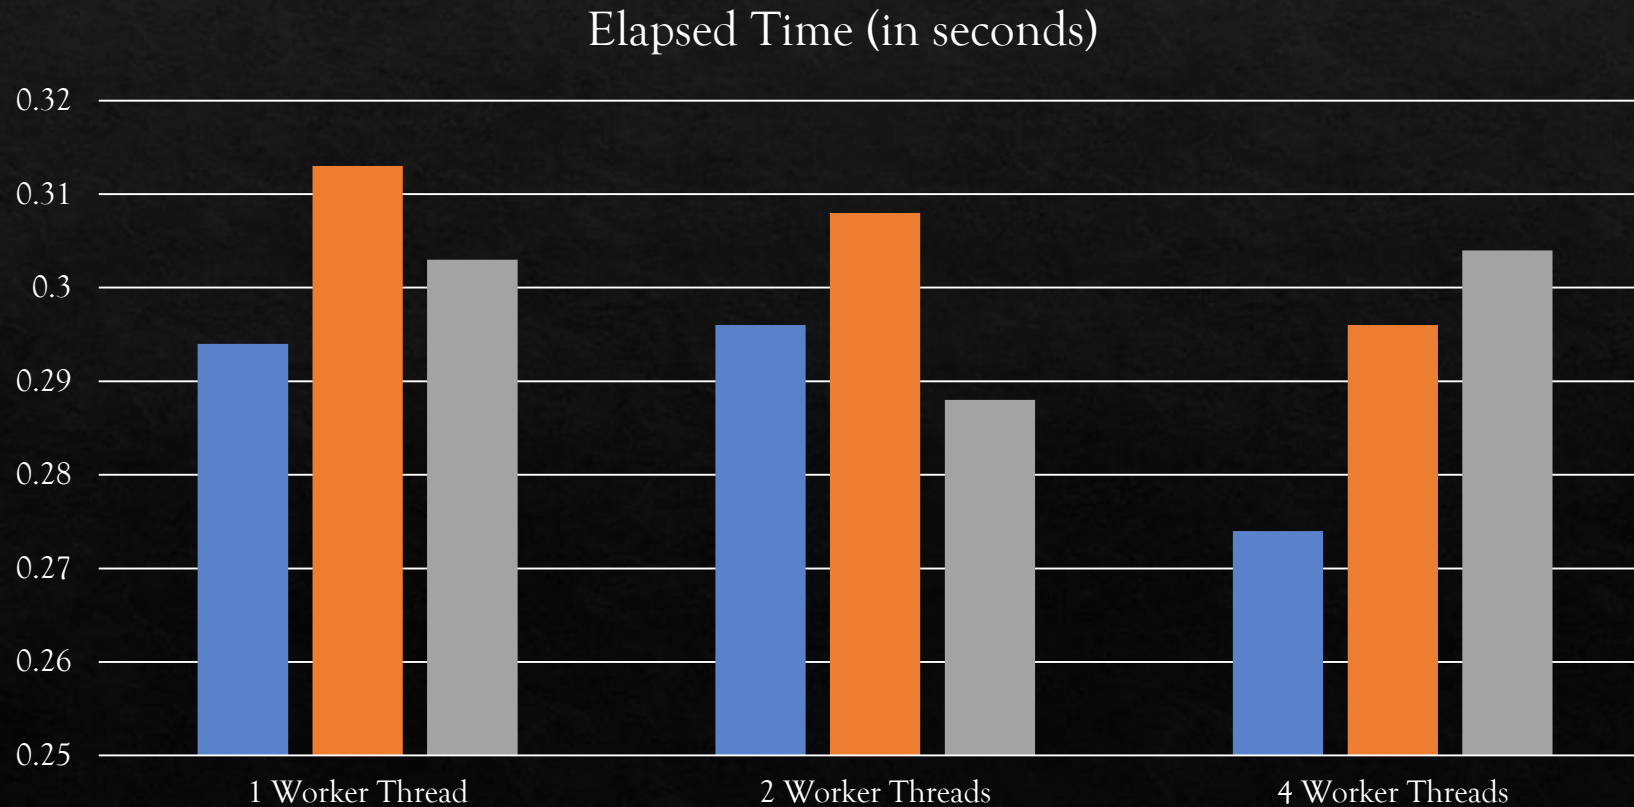

99276 – Tiago Lucas

General Problem 1

- ◆ In this problem, we are presented with a list of files and should iterate over the data to count the number of vowels per word, categorized by the word length.
- ◆ The function that does this is called “processing”.

General Problem 1

◇ The performance, using the target files provided, is as follows:

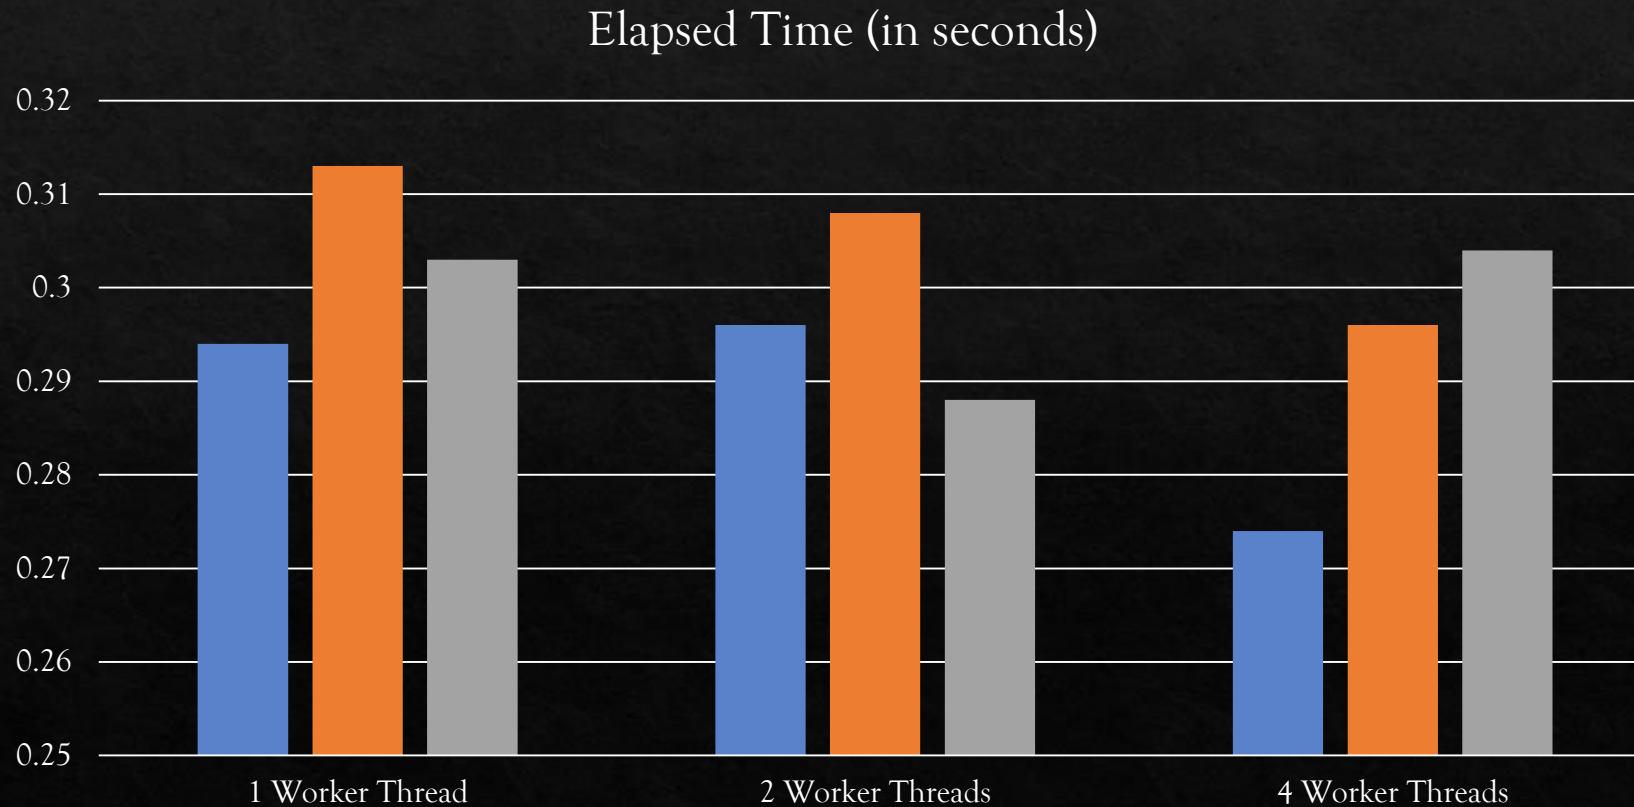

General Problem 2

- ◆ In this problem, we are presented with a list of files containing signals. The goal is to retrieve the signals, pair them and calculate the circular cross-correlation of the pair. This result shall be compared to the ones saved in the same file and the differences pointed out.
- ◆ The function that produces the results is called “circularCrossCorrelation” and the one that finds differences is called “printResults”.

General Problem 2

◇ The performance, using the target files provided, is as follows:

Conclusions

- ◆ The use of multithreading may not always be beneficial. Of course, on the flip side, some jobs gain a lot when it is well implemented.
- ◆ There should be a previous analysis, accounting the expected processing times and the time lost in transmission of data, to evaluate the use of multithreading.
